 AB - J11106552 A fine porous film is made of a polyolefin composition including more than 1 wt.% of polyolefin of ultrahigh molecular wt. of more than 5×10^5 of wt. average molecular wt, and 5 - 40 wt.% of an acryl monomer is graft polymerised on the pore surfaces of the polyolefin fine porous film of more than 50 % of porosity and < 60 Gurley sec. of air permeability, and the film surface.
 - USE - Effectively used for a separator of a battery, a diaphragm of an electrolytic condensor, a separation membrane, a water treatment membrane, the water vapour permeable water proof clothing, and a reverse osmosis filtering membrane..
 - ADVANTAGE - The hydrophilic polyolefin fine porous film of high strength and high permeability can be provided.

 AB - PROBLEM TO BE SOLVED: To obtain a high-strength high-permeability hydrophilic microporous membrane by grafting a specified amount of an acrylic monomer onto the surface and pore surfaces of a microporous membrane made from a polyolefin composition containing an at least specified amount of an ultrahigh-molecular- weight polyolefin and having a specified porosity and a specified air permeability.
 - SOLUTION: 5-40 wt.% acrylic monomer is grafted onto the pore surfaces and surface of a microporous membrane made from a polyolefin composition containing at least 1 wt.% ultrahigh-molecular-weight polyolefin having a weight- average molecular weight of 5×10^5 or above and having a porosity of 50% or above and an air permeability of 60 Gurley sec or below. The microporous polyolefin membrane is made by extruding a solvent solution of a polyolefin composition having a specified composition to form a film, removing the solvent from the film and heat-setting it. The acrylic monomer is grafted onto its surface after the surface is treated by irradiation with an ionizing radiation. The acrylic monomer is exemplified by a (meth)acrylic acid (ester) desirably in combination with a crosslinking agent, Mohr's salt and water/alcohol.
